

# Use of Molecular Markers for Breeding PCN Resistance in the Russet Market Class

Joe Kuhl - University of Idaho

Louise-Marie Dandurand - University of Idaho

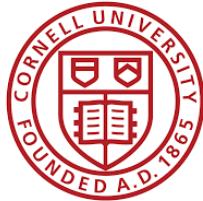

Richard Novy - USDA-ARS, Aberdeen

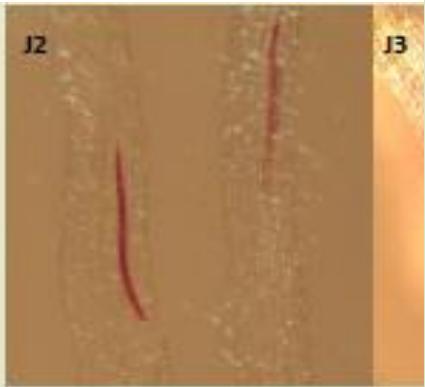

Jonathan Whitworth - USDA-ARS, Aberdeen

Inga Zasada – USDA-ARS, Corvallis

Walter DeJong - Cornell University

Xiaohong Wang - USDA-ARS, Ithaca

*G. pallida* in potato roots (L.M. Dandurand)

*G. ellingtonae* cyst on potato root (I. Zasada)

# Potato Cyst Nematode U.S. History

- *G. rostochiensis* (quarantined) [aka Golden]
  - first detected on Long Island, NY, USA. Symptoms evident since late 1930s
- *G. pallida* (quarantined) [aka Pale]
  - Idaho, USA detected in 2006
- *G. ellingtonae* (not quarantined) [aka unnamed]
  - Oregon and Idaho, USA detected in 2008

# Objectives

- Identify potato cyst nematode resistance to multiple species
- Use results to develop populations for further resistance work
- Develop oblong russets with nematode resistance for the western market

# Overview of PCN Resistance

- **14 loci (genes) mapped to eight different chromosome regions**
- **Derived from multiple relatives of cultivated potato**

## ***G. rostochiensis* (Golden cyst)**

- Major gene, *H1*, confers complete resistance to primary pathotypes (Ro1 and Ro4)
- Discovery in 1952 from *S. tuberosum* ssp. *andigena*
- Mapped to chromosome 5 and marker identified to aid in selection
- Present in many commercial varieties

## ***G. ellingtonae***

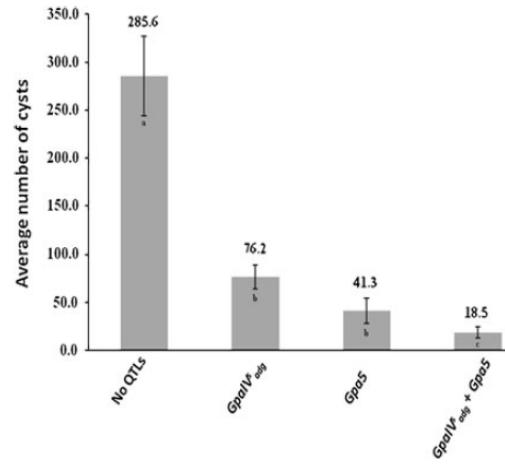

- *H1* also appears to be associated with conferring resistance to *G. ellingtonae*

## ***G. pallida* (Pale cyst)**

- More complicated resistance-polygenic
- Major contributing resistance gene (*Gpa5*) found on chromosome 5; marker also associated with it
- *GpaIV<sup>s</sup>adg* as well with associated molecular marker
- Additional genes as well contributing, although the two above are primary sources of *pallida* resistance currently in cultivars

Mol Breeding (2013) 31:921–930

# Populations

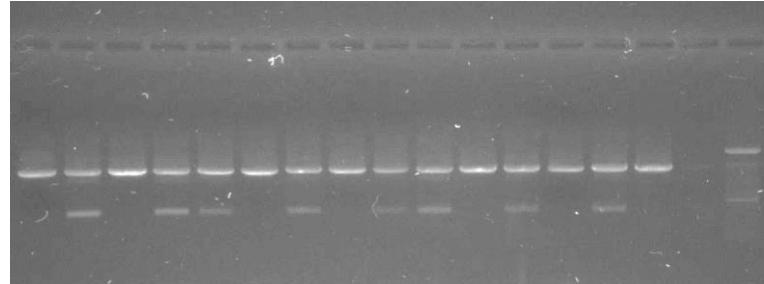

- Eden x Western Russet
  - A10915, 234 progeny
  - Resistance from *S. tuberosum* ssp. *andigena*
- Bill Brodie, Robert Plaisted, Maria Scurrah
  - Brodie et al. 1991; Brodie et al. 2000
  - NYW69, 72 and 73 populations submitted to NRSP-6 in 2000
  - Resistance from *S. tuberosum* ssp. *andigena* and *S. vernei* (International Potato Center)

# Conclusions

- Few cultivars combine  $GpaV_{adg}$  with resistance loci on chromosome 5
  - Exception: Tokio
- Markers on chromosome 5 suggest that SPUD 5000 is between HC and SPUD 1636
- Few cultivars have all three loci on chromosome 5
  - Exceptions: Arsenal and Performer
- NYW populations contain many of the markers used to track resistance in European cultivars

# Future Work

- Phenotypic responses need to be correlated with marker results
- Additional resistance sources and molecular markers are needed to increase genetic diversity
- New populations could be used to track molecular marker and phenotypic segregation
